Arterial V/C Calculations

I-290 Study area 2010 Arterial AADT and V/C ratio calculation methodology

The model provided Volume and Capacity for the entire network. Five arterials in the I-290 corridor were selected for review: North Avenue, Lake Street, Madison Street, Roosevelt Road and Cermak Road. The segments of these roads selected for review were between Wolf Road to Cicero Avenue.

Two hour capacity and volume data for AM and PM peak periods were extracted from the model for each link comprising the arterials and converted to a 1 hour period from which the initial model V/C ratio was calculated.

To calibrate the model output with reported data, the model volumes (two hour) were reduced by half to represent a one hour period and an adjustment factor was calculated using IDOT's 2009 AADT traffic volumes for the arterials. As commonly accepted, 10% of the AADT value was assumed to represent the daily 1 hour peak period volume for 2009. The V/C adjustment factor was then determined by dividing the AADT peak hour volume by the adjusted model output peak hour volume.

The V/C adjustment factor was applied to the model V/C factor for each segment sub-link, then summarized at the segment level on a link length weighted basis.

2010 Arterial PM Peak Period v/c Segment Summary							
Arterial Segment		Capacity	Model 1 hr Vol	AADT 1 hr Vol.	Vol. Ratio	Model v/c	Adjusted v/c
